## 1 Dijkstra's Algorithm

#### 1.1 Pseudocode

Given input graph g and source node s with types:

g: Graph gsize weight

s: Node gsize

We denote (u, v) as an edge from node u to v, weight(u, v) as the weight of edge (u, v). We define unexplored as the list of unexplored nodes, and dist as the list storing distance from s to each node  $n \in g$ 

```
(initially unexplored contains all nodes in graph g) unexplored : List(Node\ gsize) unexplored = \{v:v\in g\}
```

(node value is used to index dist, initially distance of all nodes are infinity except the source node)  $dist: List \ weight \\ dist[s] = 0, dist[a] = infinity, \forall a \in g, a \neq s$ 

The Dijkstra's Algorithm runs as follows: Given graph g and source node s, dist stores the distance value from s to all nodes in g calculated by the Dijkstra's algorithm, dist[v] gives the corresponding distance value of v from s. We index unexplored and dist by the number of iterations. Specifically, denote  $u_i$  as the node being explored at the  $i^th$  iteration, and denote  $dist_i$ ,  $unexplored_i$  as the value of distance list and unexplored list at the beginning of the  $i^{th}$  iteration. Then during each iteration the Dijkstra's Algorithm calculates dist, unexplored, explored as follows:

choose 
$$u_k \in unexplored_k$$
 and  $\forall u' \in unexplored_k, dist_k[u_k] \leq dist_k[u']$   $unexplored_{k+1} = unexplored_k - \{u_k\}$   $\forall v \in g$ ,

$$dist_{k+1}[v] = \begin{cases} min(dist_k[v], (dist_k[u_k] + weight(u_k, v))), & (u_k, v) \in g \\ dist_k[v] & otherwise \end{cases}$$

## 1.2 Assumptions

- 1. Weight of edges are positive
- 2. Distance value can only be zero, infinity, or summation of edge weights
- 3. All nodes n and edge e are valid:  $n, e \in q$

## 2 Definition

#### Definition 2.1. Path

(We adopt the definition of path presented in the Discrete Mathematics with Applications book by SUSANNA S. EPP.)

A path from node v to w is a finite alternating sequence of adjacent vertices and edges of G, which does not contain any repeated edge or vertex. A path from v to w has the form:

$$ve_0v_0e_1v_2....v_{n-1}e_nw$$

where  $e_i$  is an edge in g with endpoints  $v_{i-1}, v_i$ . We denote the set of paths from v to w as path(v, w).

#### Definition 2.2. Prefix of Path

Given a path from node v to  $w: p(v, w) = ve_0v_0e_1v_2...v_{n-1}e_nw$ , the prefix of this v - w path is defined as the subsequence of p(v, w) that starts with v and ends with some node  $w' \in p(v, w)$  (w' is a vertex in the sequence p(v, w)).

#### Definition 2.3. Length of Path

The length of a path  $p = ve_0v_0e_1v_2...v_{n-1}e_nw$  is the sum of the weights of all edges in p. We write:

$$length(p) = \sum weight(e_i), \forall e_i \in p.$$

### Definition 2.4. Shortest Path

Denote  $\Delta(s,v)$  as the shortest path from s to v, and  $\delta(v)$  as the length of  $\Delta(s,v)$ .  $\Delta(s,v)$  must fulfills:

$$\Delta(s,v) \in path(s,v)$$
 and 
$$\forall p' \in path(s,v), \, \delta(v) = length(\Delta(s,v)) \leq length(p')$$

## 3 Proof of Correctness

#### 3.1 Proof of Termination

The inner for loop is guaranteed to terminate as the algorithm goes through each adjacent node exactly once. As the size of list unexplored decreases by one during each iteration of the while loop, the algorithm is guaranteed to terminate.

#### 3.2 Proof of Correctness

Denote explored as the list of nodes in g but not in unexplored, i.e., explored stored all nodes whose neighbors have been updated by the algorithm. We index explored by the number of iterations, such that explored<sub>i</sub> denotes the value of explored at the beginning of the  $i^{th}$  iteration.

**Lemma 3.1.** Given any two nodes v, w, the prefix of the shortest path  $\Delta(v, w)$  is also a shortest path.

*Proof.* We will prove Lemma 3.1 by contradiction.

Consider any node q in the sequence of  $\Delta(v, w)$ , we have  $\Delta(v, w) = ve_0v_0e_1v_2...v_iqv_j....v_{n-1}e_nw$ . Suppose the prefix of  $\Delta(v, w)$  from v to q, denote as p(v, q), is not the shortest path from v to q. Then we know  $p(v, q) = ve_0v_0e_1v_2...v_iq$  is a path from v to q and  $length(p(v, q)) > length(\Delta(v, q))$ .

Based on the definition of shortest path, we know:

$$length(\Delta(v, w)) \le length(p), \forall p \in path(v, w)$$

Fenote the path after the node q as  $p(q, w) = qv_j...v_{n-1}e_nw$ , since  $\Delta(v, w) = ve_0v_0e_1v_2...v_iqv_j...v_{n-1}e_nw$ , then  $\Delta(v, w) = p(v, q) + p(q, w)$ , and that  $length(\Delta(v, w)) = length(p(v, q)) + length(p(q, w))$ . Then we have:

$$length(\Delta(v, w)) = length(p(v, q)) + length(p(q, w)) \le length(p), \forall p \in path(v, w)$$

Since p(v,q) is not the shortest path from v to q by assumption, there exists another v-w path p'(v,w) such that:

```
\begin{split} p'(v,w) &\in path(v,w) \\ p'(v,w) &= \Delta(v,q) + p(q,w) \\ length(p'(v,w)) &= length(\Delta(v,q)) + length(p(q,w)) \\ &< length(p(v,q)) + length(p(q,w)) \\ \text{i.e. } length(p'(v,w)) &< length(\Delta(v,w)) \end{split}
```

Hence we have reached a contradiction. Thus by the principle of prove by contradiction, for any the prefix p(v,q) of  $\Delta(v,w)$  is the shortest path from v to q. Lemma 3.1 holds.

**Lemma 3.2.** After the  $n^{th}$  iteration for  $n \ge 1$ , for all node  $v \in explored_{n+1}$ , if  $dist_{n+1}[v] \ne infinity$ , then  $dist_{n+1}[v]$  is the length of some s-v path, i.e,  $path(s,v) \ne \emptyset$ .

*Proof.* We will prove Lemma 3.2 by inducting on the number of iterations.

Let P(n) be: After the  $n^{th}$  iteration,  $n \ge 1$ , for all node  $v \in g$ , if  $dist_{n+1}[v] \ne infinity$ , then  $dist_{n+1}[v]$  is the length of some s - v path.

**Base Case**: We shall show P(1) holds.

Based on the algorithm, initially  $dist_1[s] = 0$  and for all node  $v \in g, v \neq s, dist_1[v] = infinity$ , then s is the only node whose distance value is not infinity. Based on the definition of path, the path from the source node s to itself is  $s, path(s, s) = \{s\}$ . Hence P(1) holds.

**Inductive Hypothesis**: Suppose  $\forall i, 1 \leq i \leq k$ , P(i) holds. That is, after the  $i^{th}$  iteration,  $1 \leq i \leq k$ , for all nodes  $v \in g$ , if  $dist_{i+1}[v] \neq infinity$ , then  $dist_{n+1}[v]$  is the length of some s-v path.

**Inductive Step:** We shall show P(k+1) holds.

For node  $u_{k+1}$  being explored during the  $(k+1)^{th}$  iteration, based on the algorithm,  $dist_{k+1}[u_{k+1}]$  is calculated as:

$$dist_{k+2}[u_{k+1}] = \begin{cases} min(dist_{k+1}[u_{k+1}], dist_{k+1}[u_{k+1}] + weight(u_{k+1}, u_{k+1})), & (u_{k+1}, u_{k+1}) \in g \\ dist_{k+1}[u_{k+1}] & otherwise \end{cases}$$

Since the distance value from  $u_{k+1}$  to itself is 0, then  $dist_{k+2}[u_{k+1}] = dist_{k+1}[u_{k+1}]$ , and that  $dist_{k+2}[u_{k+1}]$  and  $dist_{k+1}[u_{k+1}]$  are the length of the same  $s - u_{k+1}$  path if there exists one.

If  $dist_{k+2}[u_{k+1}] \neq infinity$ , then  $dist_{k+1}[u_{k+1}] = dist_{k+2}[u_{k+1}] \neq infinity$ . Since  $k \leq k$  and  $dist_{k+1}[u_{k+1}] \neq infinity$ , then based on the inductive hypothesis,  $dist_{k+1}[u_{k+1}]$  is the length of some  $s - u_{k+1}$  path, and hence  $dist_{k+2}[u_{k+1}]$  is the length of some  $s - u_{k+1}$  path.

Then for all node  $v \in g$  other than  $u_{k+1}$ , there are two cases: (1)  $(u_{k+1}, v) \in g$ ; (2)  $u_{k+1}$  does not have an edge to v. We will prove P(k+1) holds in both cases separately.

## Case (1): $(u_{k+1}, v) \in g$

Based on the algorithm, as  $(u_{k+1}, v) \in g$ ,  $dist_{k+2}[v] = min(dist_{k+1}[v], dist_{k+1}[u_{k+1}] + weight(u_{k+1}, v))$ .

- If  $dist_{k+1}[v] < dist_{k+1}[u_{k+1}] + weight(u_{k+1}, v)$ , then  $dist_{k+2}[v] = dist_{k+1}[v]$ . Then if  $dist_{k+2}[v] \neq infinity$ , we have  $dist_{k+1}[v] \neq infinity$ , and that  $dist_{k+2}[v]$  and  $dist_{k+1}[v]$  are the length of the same s-v path if there exists one. Since  $dist_{k+1}[v] \neq infinity$ , the inductive hypothesis implies that  $dist_{k+1}[v]$  is the length of some s-v path, hence  $dist_{k+2}[v]$  is the length of some s-v path. P(k+1) holds.
- If  $dist_{k+1}[v] \ge dist_{k+1}[u_{k+1}] + weight(u_{k+1}, v)$ , then  $dist_{k+2}[v] = dist_{k+1}[u_{k+1}] + weight(w, v)$ . If  $dist_{k+2}[v] \ne infinity$ , then it follows that  $dist_{k+1}[u_{k+1}] = dist_{k+2}[v] weight(u_{k+1}, v) \ne infinity$ . Then the inductive hypothesis implies that  $dist_{k+1}[u_{k+1}]$  must be the length of some  $s u_{k+1}$  path, denote as  $p(s, u_{k+1})$ . Since there is an edge  $(u_{k+1}, v) \in g$ , then  $dist_{k+2}[v] = dist_{k+1}[u_{k+1}] + weight(u_{k+1}, v)$  must be the length of the s v path through  $u_{k+1}$ . P(k+1) holds.

Hence P(k+1) holds under under Case(1).

## Case (2): $u_{k+1}$ does not have an edge to v

Under this case, our algorithm indicates that  $dist_{k+2}[v] = dist_{k+1}[v]$ , and that  $dist_{k+1}[v]$  and  $dist_{k+2}[v]$  are the length of the same s-v path if there exists one. If  $dist_{k+1}[v] = dist_{k+2}[v] \neq infinity$ , then based on the inductive hypothesis,  $dist_{k+1}[v]$  is the length of some s-v path, and hence  $dist_{k+2}[v]$  is the length of some s-v path. P(k+1) holds under Case(2).

We have proved P(k+1) holds for  $u_{k+1}$  and both cases for all nodes  $v \in g$  other than  $u_{k+1}$ . Hence by the principle of prove by induction, P(n) holds. Thus Lemma 3.2 holds.

**Lemma 3.3.** For any node  $v \in g$ , if after the  $i^{th}$  iteration,  $dist_{i+1}[v] = \delta(v)$ , then for each proceeding  $j^{th}$  iteration, j > i,  $dist_{j+1}[v] = dist_{i+1}[v] = \delta(v)$ .

*Proof.* We will prove Lemma 3.3 by induction on the number iterations after the  $i^{th}$  iteration.

Let P(n) be: For any node  $v \in g$ , if after the  $i^{th}$  iteration,  $dist_{i+1}[v] = \delta(v)$ , then for the  $(i+n)^{th}$  iteration,  $n \ge 1$ ,  $dist_{i+n+1}[v] = dist_{i+1}[v] = \delta(v)$ 

Base Case: We shall show P(1) holds.

During the  $(i+1)^{th}$  iteration, suppose  $u_{i+1}$  is the node being explored, then  $dist_{i+2}[v]$  is calculated as:

$$dist_{i+2}[v] = \begin{cases} min(dist_{i+1}[v], dist_{i+1}[u_{i+1}] + weight(u_{i+1}, v)), & (u_{i+1}, v)) \in g \\ dist_{i+1}[v] & otherwise \end{cases}$$

If  $(u_{i+1}, v) \in g$ , then if  $dist_{i+1}[u_{i+1}]$  is the length of some  $s - u_{i+1}$  path, then  $(dist_{i+1}[u_{i+1}] + weight(u_{i+1}, v))$  is the length of some s - v path. Since  $dist_{i+1}[v] = \delta(v)$ , then based on the definition of shortest path,  $dist_{i+1}[v] \le dist_{i+1}[u_{i+1}] + weight(u_{i+1}, v)$ , and hence  $dist_{i+2}[v] = dist_{i+1}[v] = \delta(v)$ .

If  $u_{i+1}$  does not have an edge to v, then  $dist_{i+2}[v] = dist_{i+1}[v] = \delta(v)$ .

Hence in either cases,  $dist_{i+2}[v] = dist_{i+1}[v] = \delta(v)$ . P(1) holds.

**Inductive Hypothesis**: Suppose P(k) holds, that is, if after the  $i^{th}$  iteration,  $dist_{i+1}[v] = \delta(v)$ , then for the  $(i+k)^{th}$  iteration,  $n \geq 1$ ,  $dist_{i+k+1}[v] = dist_{i+1}[v] = \delta(v)$ .

**Inductive Step:** We shall show P(k+1) holds.

For the node  $u_{i+k+1}$  being explored during the  $(i+k+1)^{th}$  iteration, there are two cases: (1)  $(u_{i+k+1}, v) \in g$ ; (2)  $u_{i+k+1}$  does not have an edge to v. We will show that P(k+1) holds under both cases separately.

Case 1:  $(u_{i+k+1}, v) \in g$ 

If  $u_{i+k+1}$  has an edge to v, then based on the algorithm, for  $dist_{i+k+2}[v]$ , we have:

$$dist_{i+k+2}[v] = min(dist_{i+k+1}[v], dist_{i+k+1}[u_{i+k+1}] + weight(u_{i+k+1}, v))$$

Since based on our inductive hypothesis,  $dist_{i+k+1}[v] = dist_{i+1}[v] = \delta(v)$ , then if  $dist_{i+k+1}[u_{i+k+1}]$  is the length of some  $s - u_{i+k+1}$  path, then  $(dist_{i+k+1}[u_{i+1}] + weight(u_{i+k+1}, v))$  is the length of some s - v path, and hence  $dist_{i+k+1}[v] = \delta(v) \leq (dist_{i+k+1}[u_{i+1}] + weight(u_{i+k+1}, v))$ . Then:

$$dist_{i+k+2}[v] = min(dist_{i+k+1}[v], dist_{i+k+1}[u_{i+k+1}] + weight(u_{i+k+1}, v))$$
  
=  $dist_{i+k+1}[v]$   
=  $dist_{i+1}[v] = \delta(v)$ 

P(k+1) holds under Case 1.

Case 2:  $u_{i+k+1}$  does not have an edge to v

Since  $u_{i+k+1}$  does not have an edge to v, then  $dist_{i+k+2}[v] = dist_{i+k+1}[v]$ . Based on the inductive hypothesis,  $dist_{i+k+1}[v] = dist_{i+1}[v] = \delta(v)$ . then  $dist_{i+k+2}[v] = dist_{i+1}[v] = \delta(v)$ . P(k+1) holds for Case (2). Thus P(k+1) holds. By the principle of prove by induction, P(n) holds. Lemma 3.3 proved.

**Lemma 3.4.** Assume g is a connected graph, that the source node s has a path to every node in g. After the  $n^{th}$  iteration of the algorithm for  $n \ge 1$ , for all node  $v \in explored_{n+1}$ , we have:

1.  $\delta(v) \leq \delta(v'), \forall v' \in unexplored_{n+1}$ .

5

2.  $dist_{n+1}[v] = \delta(v)$ 

*Proof.* We will prove Lemma 3.4 by inducting on the number of iterations.

Let P(n) be: After the  $n^{th}$  iteration of the algorithm for  $n \geq 1$ , for all node  $w \in explored_{n+1}$ : (1)  $\delta(w) \leq \delta(w'), \forall w' \in unexplored_{n+1}$ ; (2)  $dist_{n+1}[w] = \delta(w)$ .

Base Case: We shall show P(1) holds

Based on the algorithm, during the first iteration, the node with minimum distance value is the source node s with  $dist_1[s] = 0$ . Hence during the first iteration, only s is removed from  $unexplored_1$  and added to  $explored_2$ . Since all edge weights are non-negative, then the shortest distance value from s to s is indeed 0, hence  $dist_2[s] = 0 = \delta(s)$  and  $\delta(s) \leq \delta(v')$ ,  $\forall v' \in unexplored_2$ . P(1) holds.

**Inductive Hypothesis**: Suppose P(i) is true for all  $1 \le i \le k$ . That is, after the  $i^{th}$  iteration forall  $1 < i \le k$ , forall node  $w \in explored_{i+1}$ : (1)  $\delta(w) \le \delta(w')$ ,  $\forall w' \in unexplored_{i+1}$ ; (2)  $dist_{i+1}[w] = \delta(w)$ ;

**Inductive Step**: We shall show P(k+1) holds. That is, for all node  $w \in explored_{k+2}$ , (1)  $\delta(w) \leq \delta(w')$ ,  $\forall w' \in unexplored_{k+2}$ ; (2)  $dist_{k+2}[w] = \delta(w)$ ;

Suppose  $u_{k+1}$  is the node added into explored during the  $(k+1)^{th}$  iteration, then  $explored_{k+2} = explored_{k+1} \cup \{u_{k+1}\}$ . We will show that (1) and (2) holds for all nodes in  $explored_{k+1}$  in Part (a), and Part (b) proves (1) and (2) holds for  $u_{k+1}$ , so that (1) and (2) holds forall nodes in  $explored_{k+2}$ .

• Part(a): WTP: After the  $(k+1)^{th}$  iteration,  $\forall w \in explored_{k+1}$ , (1) and (2) holds.

Consider each node  $q \in (explored_{k+1} \cap explored_{k+2}) = explored_{k+1}$ , q must be explored before the  $(k+1)^{th}$  iteration. Suppose q is explored during the  $i^{th}$  iteration for some i < k+1, then based on our inductive hypothesis,  $dist_{i+1}[q] = \delta(q)$ , and  $\delta(q) \leq \delta(q'), \forall q' \in unexplored_{i+1}$ .

Proof of (1): Based on the algorithm, for each iteration, the algorithm explores exactly one node and never revisits any explored nodes. For each node  $q \in explored_{k+1}$  mentioned above, since q is explored before the  $(k+1)^{th}$  iteration, then  $unexplored_{k+1} \subseteq unexplored_{i+1}$ . Since  $\delta(q) \leq \delta(q'), \forall q' \in unexplored_{i+1}$ , and  $unexplored_{i+1}$  includes all node in  $unexplored_{k+1}$ , then  $\delta(q) \leq \delta(q'), \forall q' \in unexplored_{k+1}$ . (1) holds for  $explored_{k+1}$ .

Proof of (2): For all proceeding  $j^{th}$  iterations, j > i, suppose node q'' is the node being explored for the  $j^{th}$  iteration, then the value of  $dist_{j+1}[q]$  is calculated as:

$$dist_{j+1}[q] = \begin{cases} min(dist_{j}[q], dist_{j}[q''] + weight(q'', q)), & (q'', q) \in g \\ dist_{j}[q] & otherwise \end{cases}$$

Since  $dist_{i+1}[q] = \delta(q) \leq length(p)$  for all path p from s to q, then for each proceeding  $j^{th}$  iteration after the  $i^{th}$  iteration, there does not exists such q'' such that  $dist_j[q''] + weight(q'', q) < \delta(q) = dist_{i+1}[q]$ . Hence  $dist_{j+1}[q] = \delta(q) = dist_{i+1}[q], \forall j > i$ . Since k+1 > i, then for all  $q \in S$ ,  $dist_{k+1} = \delta(q) = dist_{i+1}[q]$ . (2) holds for  $explored_{k+1}$ .

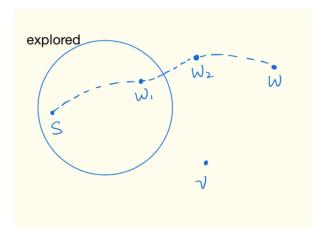

Hence we have proved that both (1) and (2) holds for all nodes in  $explored_{k+1}$ .

• Part(b): After the  $(k+1)^{th}$  iteration, (1) and (2) holds for  $\{u_{k+1}\}$ . We want to show: (1)  $\delta(u_{k+1}) \leq \delta(v')$ ,  $\forall v' \in unexplored_{k+2}$ , and (2)  $dist_{k+1}[u_{k+1}] = \delta(u_{k+1})$ . 1.  $\delta(u_{k+1}) \leq \delta(v'), \forall v' \in unexplored_{k+2}$ 

We will prove (1) by contradiction. Suppose there exists  $w \in unexplored_{k+2}$ , such that  $\delta(u_{k+1}) > \delta(w)$ .

The assumption states that source s has a path to every node in g, then  $dist_{k+1}[u_{k+1}] \neq infinity$ . Thus Lemma 3.2 implies that  $dist_{k+1}[u_{k+1}]$  is the length of some s-v path. Based on the definition of shortest path,  $\delta(u_{k+1}) \leq dist_{k+1}[u_{k+1}]$ . Since  $\delta(u_{k+1}) > \delta(w)$  and  $\delta(u_{k+1}) \leq dist_{k+1}[u_{k+1}]$ , then we have  $\delta(w) < dist_{k+1}[u_{k+1}]$  ([NE1]).

Consider the shortest path  $\Delta(s, w)$  from s to w,  $\delta(w) = length(\Delta(s, w))$ . Since  $w \notin explored_{k+2}$ , then there must exists some node in  $\Delta(s, w)$  that are not in  $explored_{k+2}$ . Suppose the first node along  $\Delta(s, w)$  that is not in the  $explored_{k+2}$  list is  $w_2$ , and the node right before  $w_2$  in the s to  $w_2$  subpath is  $w_1$ , thus  $w_1 \in explored_{k+2}$ . The image below illustrates this construction:

Denote the subpath from s to  $w_1$  in  $\Delta(s,w)$  as  $p(s,w_1)$ , subpath from s to  $w_2$  in  $\Delta(s,w)$  as  $p(s,w_2)$ , and subpath  $w_2$  to w as  $p(w_2,w)$ . Based on Definition 2.2 Prefix of Path,  $p(s,w_1)$  is a prefix of  $\Delta(s,w)$ . Since  $p(s,w_1)$  is the prefix of the shortest s-w path, then based on Lemma 3.1,  $p(s,w_1)$  is the shortest path from s to  $w_1$ ,  $\Delta(s,w_1)=p(s,w_1)$ ,  $length(p(s,w_1))=\delta(w_1)$ . Similarly, since  $p(s,w_2)=p(s,w_1)+(w_1,w_2)$ , then  $p(s,w_2)$  is a prefix of  $\Delta(s,w)$ , and hence Lemma 3.1 implies that  $p(s,w_2)$  is the shortest path from s to  $w_2$ . Then we have:

$$\Delta(s, w_2) = p(s, w_2) = p(s, w_1) + (w_1, w_2) 
\delta(w_2) = length(\Delta(s, w_2)) 
= length(p(s, w_2)) 
= length(p(s, w_1)) + weight(w_1, w_2) 
= \delta(w_1) + weight(w_1, w_2) \text{ ([E1])}$$

For  $\Delta(s, w)$  we have:

$$\begin{split} \delta(w) &= length(p_w) \\ &= length(p(s, w_1)) + weight(w_1, w_2) + length(p(w_2, w)) \\ &= \delta(w_1) + weight(w_1, w_2) + length(p(w_2, w)) \end{split}$$

Since all edge weights are positive, then:

$$\delta(w_2) = \delta(w_1) + weight(w_1, w_2) \le \delta(w)$$
 ([E2])

Since  $w_1 \in explored_{k+2}$ , there are two cases to consider:  $w_1 = u_{k+1}$  and  $w_1 \neq u_{k+1}$ . We will prove P(k+1) under both cases below.

Case 1:  $w_1 = u_{k+1}$ 

When  $w_1 = u_{k+1}$ , then substitude  $w_1$  by  $u_{k+1}$  in [E2], we have:

$$\delta(w_1) + weight(w_1, w_2) = \delta(u_{k+1}) + weight(u_{k+1}, w_2) \le delta(w)$$
 i.e.  $\delta(u_{k+1}) \le \delta(w)$ 

which contradicts with our assumption that  $\delta(u_{k+1}) > \delta(w)$ . Hence by the principle of prove by contradiction,  $\delta(u_{k+1}) < \delta(w)$ . (1) holds for P(k+1).

Case 2:  $w_1 \neq u_{k+1}$ 

Since  $w_1 \in explored_{k+2}$  and  $w_1 \neq u_{k+1}$ ,  $w_1$  is explored before the  $(k+1)^{th}$  iteration. i.e.,  $w_1 \in explored_{k+1}$ . Suppose  $w_1$  is being explored during the  $i^{th}$  iteration, i < k+1, then based on the algorithm, the value of  $dist_{i+1}[w_1]$  is calculated as:

$$dist_{i+1}[w_1] = \begin{cases} min(dist_i[w_1], dist_i[w_1] + weight(w_1, w_1)), & (w_1, w_1) \in g \\ dist_i[w_1] & otherwise \end{cases}$$

Thus  $dist_{i+1}[w_1] = dist_i[w_1]$ . Since the inductive hypothesis implies that  $dist_{i+1}[w_1] = \delta(w_1)$ , then  $dist_i[w_1] = \delta(w_1)$ .

Since  $w_1$  has an edge to  $w_2$ , then  $dist_{i+1}[w_2]$  must have been updated according as follows:

$$dist_{i+1}[w_2] = min(dist_i[w_2], dist_i[w_1] + weight(w_1 + w_2))$$
  
=  $min(dist_i[w_2], \delta(w_1) + weight(w_1 + w_2))$ 

Based on [E1] we know that  $\delta(w_2) = \delta(w_1) + weight(w_1 + w_2)$ , then  $dist_{i+1}[w_2] = min(dist_i[w_2], \delta(w_2))$ . If  $dist_i[w_2] = infinity$ , then  $dist_{i+1}[w_2] = min(dist_i[w_2], \delta(w_2)) = \delta(w_2)$ . If  $dist_i[w_2] \neq infinity$ , then based on Lemma 3.2,  $dist_i[w_2]$  is the length of some  $s - w_2$  path. Since  $\delta(w_2) \leq length(p), \forall p \in path(s, w_2)$ , then  $dist_{i+1}[w_2] = min(dist_i[w_2], \delta(w_2)) = \delta(w_2)$ . Hence in either cases, we conclude that  $dist_{i+1}[w_2] = \delta(w_2)$ .

Since  $dist_{i+1}[w_2] = \delta(w_2)$  and i < k+1, then based on Lemma 3.3, we have  $dist_{k+1}[w_2] = dist_{i+1} = \delta(w_2)$ . Based on [E2],  $\delta(w_2) < \delta(w)$ , then  $dist_{k+1}[w_2] < \delta(w)$  [NE2]. Combining with [NE1], we have:

$$\delta(w) < dist_{k+1}[u_{k+1}] \text{ (from [NE1])}$$
  
$$dist_{k+1}[w_2] < \delta(w)$$

Hence  $dist_{k+1}[w_2] < dist_{k+1}[u_{k+1}]$  [NE2].

Based on our assumption, at the beginning of the  $(k+1)^{th}$  generation,  $u_{k+1}, w_2 \notin explored_{k+1}$ 

and  $u_{k+1}$  is selected by the algorithm, then we must have  $dist_{k+1}[w_2] \geq dist_{k+1}[u_{k+1}]$ , which contradicts with [NE2]. Hence by the principle of prove by contradiction, there does not exsist  $w \in unexplored_{k+2}$ , such that  $\delta(u_{k+1}) > \delta(w)$ , i.e.  $\delta(u_{k+1}) \leq \delta(w)$ ,  $\forall w \in unexplored_{k+2}$ . Hence (1) holds for  $u_{k+1}$ .

2. After the  $(k+1)^{th}$  iteration,  $dist_{k+1}[u_{k+1}] = \delta(u_{k+1})$ 

We will prove this by contradiction.

Suppose  $dist_{k+1}[u_{k+1}]$  is the length of some path p from s to  $u_{k+1}$ . Assume the shortest path from s to  $u_{k+1}$  is some path different from p, i.e.  $\Delta(s, u_{k+1}) \neq p$ ,  $\delta(u_{k+1}) \leq dist_{k+1}[u_{k+1}]([b])$ . Suppose v' is the node just before  $u_{k+1}$  in  $\Delta(s, u_{k+1})$ .

$$\delta(u_{k+1}) = \delta(v') + weight(v', u_{k+1}) < dist_{k+1}[u_{k+1}]$$
 Since all edge weights are non-negative, then:  $\delta(v') \leq \delta(u_{k+1})$ 

Based on (1), after the  $(k+1)^{th}$  iteration, for all nodes  $q \in unexplored_{k+2}$ ,  $\delta(q) \geq \delta(u_{k+1})$ , and  $\delta(v') \leq \delta(u_{k+1})$ , then v' cannot be in  $unexplored_{k+2}$ . Since  $unexplored_{k+1} = unexplored_{k+2} \cup u_{k+1}$ , then  $v' \notin unexplored_{k+1}$ . Hence at the beginning of the  $(k+1)^{th}$  iteration, v' is already explored. Since v' is explored before the  $(k+1)^{th}$  iteration and v' has an edge to  $u_{k+1}$ , then the algorithm must have considered  $(\delta(v') + weight(v', u_{k+1}))$  against  $dist_{k+1}[u_{k+1}]$  and chose  $min((\delta(v') + weight(v', u_{k+1})), dist_{k+1}[u_{k+1}])$ , which is  $dist_{k+1}[u_{k+1}]$ . Thus  $dist_{k+1}[u_{k+1}] \leq (\delta(v') + weight(v', u_{k+1}))$ , i.e.  $dist_{k+1}[u_{k+1}] \leq \delta(u_{k+1})$ , which contradicts with our assumption [b]. Hence by the principle of prove by contradiction,  $dist_{k+1}[u_{k+1}] = \delta(u_{k+1})$ . (2) holds for  $u_{k+1}$ .

Since we have proved both (1) and (2) forall nodes in  $explored_{k+1}$  after the  $(k+1)^{th}$  iteration, P(k+1) holds. Then by the principle of prove by induction, Lemma 3.4 holds.

#### *Proof.* Prove of Correctness

By applying Lemma 3.4 to the last iteration of the algorithm, we obtained that for all nodes n in the explored list, dist[n] is indeed the shortest path distance value from source s to n, hence Dijkstra's algorithm indeed calculates the shortest path distance value from the source s to each node  $n \in g$ .
